## DRUG COMBINATIONS USEFUL FOR PREVENTION OF RESTENOSIS

### Related Application:

10

This application claims benefit of a provisional application of the same title, S.N. 60/204417, filed May 12, 2000.

### Field of the Invention:

15

This invention describes the delivery of different drug combinations, either systemically or locally, particularly from an intravascular stent, directly from micropores in the stent body or mixed or bound to a polymer coating applied on stent, to inhibit neointimal tissue proliferation and thereby prevent restenosis. This invention given either systemically or locally also facilitates the performance of the stent in inhibiting restenosis.

20

### BACKGROUND OF THE INVENTION

25

30

Atherosclerotic lesions, which limit or obstruct coronary blood flow, are the major cause of ischemic heart disease related mortality, resulting in 500,000-600,000 deaths annually. Percutaneous transluminal coronary angioplasty (PTCA) to open the obstructed artery was performed in over 550,000 patients in the U.S. and 945,000+ patients worldwide in 1996 (Lemaitre et al., 1996). A major limitation of this technique is the problem of post-PTCA closure of the vessel, both immediately after PTCA (acute occlusion) and in the long term (restenosis): 30% of patients with subtotal lesions and 50% of patients with chronic total lesions will go on to restenosis after angioplasty. Additionally,

restenosis is a significant problem in patients undergoing saphenous vein bypass graft. The mechanism of acute occlusion appears to involve several factors and may result from vascular recoil with resultant closure of the artery and/or deposition of blood platelets along the damaged length of the newly opened blood vessel followed by formation of a fibrin/red blood cell thrombus.

Restenosis after angioplasty is a more gradual process and involves initial formation of a subcritical thrombosis with release from adherent platelets of cell derived growth factors with subsequent proliferation of intimal smooth muscle cells and local infiltration of inflammatory cells contributing to vascular hyperplasia. It is important to note that multiple processes, among those including thrombosis, cell proliferation, cell migration and inflammation each seem to contribute to the restenotic process.

In the U.S., a 30 - 50% restenosis rate translates to 120,000 - 200,000 U.S. patients at risk from restenosis. If only 80% of such patients elect repeat angioplasty (with the remaining 20% electing coronary artery bypass graft) is added to the cost of coronary artery bypass graft for the remaining 20%, the total cost for restenosis easily reaches into billions of dollars. Thus, successful prevention of restenosis could result not only in significant therapeutic benefit but also in significant health care savings.

While the exact mechanism for restenosis is still uncertain, the general aspects of the restenosis process have been identified:

- 1) In the normal arterial wall, smooth muscle cells (SMC) proliferate at a low rate (<0.1%/day). SMC in vessel wall exists in a 'contractile' phenotype

5 characterized by 80-90% of the cell cytoplasmic volume occupied with the  
contractile apparatus. Endoplasmic reticulum, Golgi, and free ribosomes are  
few and located in the perinuclear region. Extracellular matrix surrounds  
SMC and is rich in heparin-like glycosylaminoglycans which are believed to  
be responsible for maintaining SMC in the contractile phenotypic state  
10 (Campbell and Campbell, 1985).

2) Upon pressure expansion of an intracoronary balloon catheter during  
angioplasty, smooth muscle cells within the arterial wall become injured,  
initiating a thrombotic and inflammatory response. Cell derived growth  
factors such as platelet derived growth factor (PDGF), basic fibroblast growth  
factor (bFGF), epidermal growth factor (EGF), thrombin, etc., released from  
platelets (i.e., PDGF) adhering to the damaged arterial luminal surface,  
invading macrophages and/or leukocytes, or directly from SMC (i.e., bFGF)  
provoke a proliferation and migratory response in medial SMC. These cells  
undergo a phenotypic change from the contractile phenotype to a 'synthetic'  
phenotype characterized by only few contractile filament bundles but  
extensive rough endoplasmic reticulum, Golgi and free ribosomes.  
Proliferation/migration usually begins within 1-2 days post-injury and peaks at  
2 days in the media, declining thereafter (Campbell and Campbell, 1987;  
25 Clowes and Schwartz, 1985).

3) Daughter synthetic cells migrate to the intimal layer of arterial smooth muscle  
and continue to proliferate and begin to secrete significant amounts of  
extracellular matrix proteins. Proliferation, migration and inflammation  
continue until the damaged luminal endothelial layer regenerates at which  
30 time proliferation slows within the intima, usually within 7-14 days postinjury.

5 The further increase in intimal thickening that occurs over the next 3-6 months is due primarily to an increase in extracellular matrix rather than cell number. Thus, SMC migration and proliferation is an acute response to vessel injury while intimal hyperplasia is a more chronic response. (Liu *et al.*, 1989).

- 10
- 4) Simultaneous with local proliferation and migration, inflammatory cells adhere to the site of vascular injury. Within 3 – 7 days post injury, luminal adherent cells decline due to migration of inflammatory to the deeper layers of the vessel wall. In animal models employing either balloon injury or stent implantation, inflammatory cells may persist at the site of vascular injury for at least 30 days (Tanaka *et al.*, 1993; Edelman *et al.*, 1998). Inflammatory cells therefore are present and may contribute to both the acute and chronic phases of restenosis.

15

20 Numerous agents have been examined for presumed antiproliferative actions in restenosis and have shown some activity in experimental animal models. Some of the agents which have been shown to successfully reduce the extent of intimal hyperplasia in animal models include: heparin and heparin fragments (Clowes, A.W. and Karnovsky M., *Nature*, 265: 25-26, 1977; Guyton, J.R. *et al.*, *Circ. Res.*, 46: 625-634, 1980; Clowes, A.W. and Clowes, M.M., *Lab. Invest.* 52: 611-616, 1985; Clowes, A.W. and Clowes, M.M., *Circ. Res.* 58: 839-845, 1986; Majesky *et al.*, *Circ Res.* 61: 296-300, 1987; Snow *et al.*, *Am. J. Pathol.* 137: 313-330, 1990; Okada, T. *et al.*, *Neurosurgery* 25: 92-98, 1989), colchicine (Currier, J.W. *et al.*, *Circulation* 80: II-66, 1989, taxol (Sollott, S.J. *et al.*, *J. Clin. Invest.* 95: 1869-1876, 1995), angiotensin converting enzyme (ACE) inhibitors (Powell, J.S. *et al.*, *Science*, 245: 186-188, 1989), angiopeptin (Lundergan, C.F. *et al.*, *Am. J. Cardiol.* 17(Suppl. B):

25

30

132B-136B, 1991), cyclosporin A (Jonasson, L. et al., Proc. Natl. Acad. Sci., 85:  
2303, 1988), goat-anti-rabbit PDGF antibody (Ferns, G.A.A., et al., Science 253:  
1129-1132, 1991), terbinafine (Nemecek, G.M. et al., J. Pharmacol. Exp. Thera. 248:  
1167-1174, 1989), trapidil (Liu, M.W. et al., Circulation 81: 1089-1093, 1990),  
tranilast (Fukuyama, J. et al., Eur. J. Pharmacol. 318: 327-332, 1996), interferon-  
gamma (Hansson, G.K. and Holm, J., Circulation 84: 1266-1272, 1991), rapamycin  
(Marx, S.O. et al., Circ. Res. 76: 412-417, 1995), steroids (Colburn, M.D. et al., J.  
Vasc. Surg. 15: 510-518, 1992), see also Berk, B.C. et al., J. Am. Coll. Cardiol. 17:  
111B-117B 1991, ionizing radiation (Weinberger, J. et al., Int. J. Rad. Onc. Biol.  
Phys. 36: 767-775, 1996), fusion toxins (Farb, A. et al., Circ. Res. 80: 542-550,  
1997) antisense oligonucleotides (Simons, M. et al., Nature 359: 67-70, 1992) and  
gene vectors (Chang, M.W. et al., J. Clin. Invest. 96: 2260-2268, 1995).  
Antiproliferative action on SMC *in vitro* has been demonstrated for many of these  
agents, including heparin and heparin conjugates, taxol, tranilast, colchicine,  
ACE inhibitors, fusion toxins, antisense oligonucleotides, rapamycin and ionizing  
radiation. Thus, agents with diverse mechanisms of SMC inhibition may have  
therapeutic utility in reducing intimal hyperplasia.

However, unlike animal models, attempts in human angioplasty patients to  
prevent restenosis by systemic pharmacologic means have thus far been  
unsuccessful. Neither aspirin-dipyridamole, ticlopidine, anticoagulant therapy  
(acute heparin, chronic warfarin, hirudin or hirulog), thromboxane receptor  
antagonism nor steroids have been effective in preventing restenosis, although  
platelet inhibitors have been effective in preventing acute reocclusion after  
angioplasty (Mak and Topol, 1997; Lang *et al.*, 1991; Popma *et al.*, 1991).  
Additionally, the 7E3 humanized monoclonal antibody fragment to the platelet  
GP IIb/IIIa receptor is still under study but has not shown promising results for

5 the reduction in restenosis following angioplasty and stenting. Other agents,  
which have also been unsuccessful in the prevention of restenosis, include the  
calcium channel antagonists, prostacyclin mimetics, angiotensin converting  
enzyme inhibitors, serotonin receptor antagonists, and antiproliferative agents.  
10 These agents must be given systemically, however, and attainment of a  
therapeutically effective dose may not be possible; antiproliferative (or anti-  
restenosis) concentrations may exceed the known toxic concentrations of these  
agents so that levels sufficient to produce smooth muscle inhibition may not be  
reached (Mak and Topol, 1997; Lang *et al.*, 1991; Popma *et al.*, 1991).

15 Additional clinical trials in which the effectiveness for preventing restenosis of  
dietary fish oil supplements or cholesterol lowering agents has been examined  
have shown either conflicting or negative results so that no pharmacological  
agents are as yet clinically available to prevent post-angioplasty restenosis (Mak  
and Topol, 1997; Franklin and Faxon, 1993; Serruys, P.W. *et al.*, 1993). Recent  
20 observations suggest that the antilipid/antioxident agent, probucol may be useful  
in preventing restenosis but this work requires confirmation (Tardif *et al.*, 1997;  
Yokoi, *et al.*, 1997). Probucol is presently not approved for use in the United  
States and a 30-day pretreatment period would preclude its use in emergency  
angioplasty. Additionally, application of ionizing radiation has shown significant  
25 promise in reducing or preventing restenosis after angioplasty in patients with  
stents (Teirstein *et al.*, 1997). Currently, however, the most effective treatments  
for restenosis are repeat angioplasty, atherectomy or coronary artery bypass  
grafting, because no therapeutic agents currently have US Federal Regulatory  
Agency (FDA) approval for use for the prevention of post-angioplasty restenosis.

5 Unlike systemic pharmacologic therapy, stents have proven useful in partially preventing restenosis. Stents, are balloon-expandable slotted metal tubes (usually, but not limited to, stainless steel), which, when expanded within the lumen of an angioplastied coronary artery, provide structural support to the arterial wall. This support is helpful in maintaining vessel lumen patency. In two  
10 randomized clinical trials, stents increased angiographic success after PTCA, by increasing minimal lumen diameter and reducing, (but not eliminating,) the incidence of restenosis at 6 months (Serruys et al., 1994; Fischman et al., 1994).

15 Additionally, in a preliminary trial, heparin coated stents appear to possess the same benefit of reduction in stenosis diameter at follow-up as was observed with non-heparin coated stents. Heparin coating also appears to have the added benefit of producing a reduction in sub-acute thrombosis after stent implantation (Serruys et al., 1996). Thus, 1) sustained mechanical expansion of a stenosed coronary artery with a stent has been shown to provide some measure of restenosis prevention, and 2) coating of stents with heparin has demonstrated  
20 both the feasibility and the clinical usefulness of delivering drugs locally, at the site of injured tissue.

25 Post-angioplasty restenosis is a multifactorial process that involves numerous interactive mechanisms. This means that effective prevention of restenosis may not be feasible with agents possessing a single mechanism of action; positive therapeutic results may be best achieved through application of several agents with differing therapeutic targets. Thus, potential therapeutic benefit could be found with the co-delivery of agents with different mechanisms  
30 of action targeting different components of the restenosis process.

5        **SUMMARY OF THE INVENTION**

10        The current invention comprises an approach to solving the clinical problem  
of restenosis, which involves the administration of drug combinations, either  
locally or systemically. One example of such a combination would be the addition  
of the antiinflammatory corticosteroid, dexamethasone, with an antiproliferative  
agent such as cladribine, rapamycin, vincristine, taxol, or a nitric oxide donor.  
Such combination therapies might result in a better therapeutic effect (less  
proliferation as well as less inflammation, a stimulus for proliferation) than would  
occur with either agent alone. Such agents could be administered systemically  
15        in their respective therapeutic doses, or, alternatively, could be bound to the  
surface of a stent by means of incorporation within either a biodegradable or  
biostable polymeric coating. Alternatively, these agents could be incorporated  
into a stent constructed with a grooved reservoir. Thus, delivery of a stent  
containing both an antiproliferative agent and an antiinflammatory agent to a  
coronary artery injured during the process of angioplasty would provide the  
added therapeutic benefit of 1) limiting the degree of local smooth muscle cell  
proliferation, 2) reducing a stimulus for proliferation, i.e., inflammation, and thus  
20        enhance the restenosis-limiting action of the stent.

25        In other embodiments of the inventions, growth factor or cytokine signal  
transduction inhibitor, such as the ras inhibitor, R115777, or a tyrosine kinase  
inhibitor, such as tyrphostin, might be combined with an antiproliferative agent  
such as taxol, vincristine or rapamycin so that proliferation of SMC could be  
inhibited by different mechanisms. Alternatively, an antiproliferative agent such  
30        as taxol, vincristine or rapamycin could be combined with an inhibitor of  
extracellular matrix synthesis such as halofuginone. In the above cases, agents

5 acting by different mechanisms could act synergistically to reduce SMC  
proliferation and vascular hyperplasia. This invention is also intended to cover  
other combinations of two or more such drug agents. As mentioned above, such  
agents could be administered systemically, delivered locally *via* drug delivery  
10 catheter, or formulated for delivery from the surface of a stent, or given as a  
combination of systemic and local therapy.

**DETAILED DESCRIPTION OF THE DRAWINGS:**

15 The invention will be better understood in connection with the following  
figures in which:

Figures 1 and 1a are top views and section views of a stent containing  
reservoirs as described in the present invention;

20 Figures 2a and 2b are similar views of an alternate embodiment of the stent  
with open ends;

Figures 3a and 3b are further alternate figures of a device containing a  
grooved reservoir;

25 Figure 4 is a layout view of a device containing a reservoir as in Figure 3; and

Figures 5 and 6 are a graph of the performance characteristics of stents  
coated according to this invention.

30

5

## **DETAILED DESCRIPTION OF THE INVENTION**

### **Multiple Drug Therapy combined with a Stent**

10

As stated previously, implantation of a coronary stent in conjunction with balloon angioplasty is highly effective in treating acute vessel closure and may reduce the risk of restenosis. Intravascular ultrasound studies (Mintz et al., 1996) suggest that coronary stenting effectively prevents vessel constriction and that most of the late luminal loss after stent implantation is due to plaque growth, probably related to neointimal hyperplasia. The late luminal loss after coronary stenting is almost two times higher than that observed after conventional balloon angioplasty. Thus, inasmuch as stents prevent at least a portion of the restenosis process, a combination of agents, which prevent inflammation and proliferation, or prevents proliferation by multiple mechanisms, combined with a stent may provide the most efficacious treatment for post-angioplasty restenosis. In this regard, a stent in conjunction with systemic treatment with the drug combinations suggested above or local delivery of such drug combinations is an attractive treatment. Either systemic or local delivery of multiple drugs from a stent has the following advantages:

15

20

25

1. Prevention of vessel recoil and remodeling through the scaffolding action of the stent;
2. Prevention of multiple components of neointimal hyperplasia, the vascular response to injury

30

Local administration of drug combinations to stented coronary arteries might have additional therapeutic benefit:

- 1) higher tissue concentrations would be achievable than would occur with systemic administration;
- 2) reduced systemic toxicity; and
- 3) single treatment/ease of administration

An additional benefit of combination drug therapy may be to reduce the dose of each of the therapeutic components and thus limiting their toxicity, while still achieving a reduction in restenosis. Combination therapy is therefore a means of improving the therapeutic ratio (efficacy/toxicity) of an antirestenosis agent.

As seen in the accompanying Figures 1-4, it is possible to modify currently manufactured stents in order to provide adequate drug delivery. As seen in Figures 1a, 2a and 3a, any stent strut 10, 20, 30 can be modified to have a certain reservoir 11, 21, 31. Each of these reservoirs can be open or closed as desired. These reservoirs can hold the drug to be delivered. Figure 4 shows a stent 40 with a reservoir 45 created at the apex of a flexible connector. Of course, this reservoir 45 is intended to be useful to deliver any drug at a specific point of flexibility of the stent. Accordingly, this concept can be useful for "second generation" type stents. Processes for coating such stents are described, for instance, in Serial Nos. 09/061,568, filed 16 Apr 1998, and 09/512,432 filed 25 Feb 2000, both of which are assigned to a common assignee and are incorporated herein by reference.

In any of the foregoing devices, however, it is useful to have the drug dosage applied with enough specificity and a sufficient concentration to provide an effective dosage in the lesion area. In this regard, the reservoir size in the stent struts must

be kept at a size of about 0.1 mm to about 1 mm depth, and 7 mm to 15 mm length, or enough to hold at least a therapeutic amount of the drug. Then, it should be possible to adequately apply the drug dosage at the desired location and in the desired amount.

### Example 1

To assess the ability of a drug combination to prevent cell proliferation, human smooth muscle cells (Clonetics, Walkersville, MD) were seeded at a density of 10,000 cells/well) into each well of 24-well plates and cultured in growth medium containing heparin, EGF (epidermal growth factor), FGF fibroblast growth factor) and serum. After 24 hours, the growth medium was changed and fresh medium containing various concentrations of test agents (0.01 - 10 mcg/mL) were added to triplicate wells. Medium was replaced with fresh medium (plus test agents) after 3 days. On day five, cells were detached by trypsin/EDTA and counted using a hemacytometer. Cell viability was assessed by trypan blue exclusion.

Table 1 provides the percent of control growth of the various tested concentrations of the antiinflammatory agent, dexamethasone, on human smooth muscle cells, either in the absence or presence of 2 concentrations of the antiproliferative/antiimmune agent, rapamycin. Dexamethasone produced a concentration-related decrease in the proliferation of smooth muscle cells in this model system. The IC<sub>50</sub> value (concentration required to produce a reduction in proliferation to 50% of the control cell count) for the inhibition of smooth muscle cells with dexamethasone alone estimated from Table 1 is 5 µg/mL. Addition of 0.2 µg/mL of rapamycin to the incubation media was found to reduce the IC<sub>50</sub> estimate of dexamethasone to 0.05

5             $\mu\text{g/mL}$ . A greater added concentration of rapamycin (2  $\mu\text{g/mL}$ ) further reduced the  
 $\text{IC}_{50}$  estimate for dexamethasone to less than 0.01  $\mu\text{g/mL}$ .

10            Thus, as the rapamycin concentration was increased in the incubation media,  
less dexamethasone was required to produce a 50% inhibition of cell growth. Since  
the amounts of rapamycin employed did not achieve a 50% inhibition of cell growth,  
Table 1 demonstrates that concentrations of both rapamycin or dexamethasone  
below their respective  $\text{IC}_{50}$  amounts may combine to produce an effect on cell growth  
greater than either agent individually. Such a drug combination may be  
therapeutically useful for inhibition of the intimal smooth muscle cell proliferation that  
15            accompanies stent implantation. While efficacy could be maintained at these lower  
doses, toxicities associated with each of these agents might be ameliorated.

TABLE 1. Inhibition of human vascular smooth muscle cell proliferation with  
dexamethasone or dexamethasone + rapamycin.

	<b>Concentration of Dexamethasone (<math>\mu\text{g/ml}</math>)</b>									
	0	0.01	0.05	0.1	0.5	1	5	10	50	100
<b>% of Control Growth</b>

overlayer; e: Rapamycin overlayer; f: Top coated

### **Example 2**

10 This example describes the preparation of a base coating that contains rapamycin

Stents were coated with Parylene C™ using a vapor deposition method provided by the manufacturer of the parylene-coating instrument (SCS Madison, Wisconsin). The stent is weighed and then mounted for coating. While the stent is rotating a solution of 1.75mg/ml Poly (ethylene-covinyl acetate)(PEVA), 1.75mg/ml polybutyl methacrylate, and 1.5mg/ml rapamycin dissolved in tetrahydrofuran is sprayed onto it. The coated stent is removed from the spray and allowed to air-dry. After a final weighing the amount of coating on the stent is determined.

### **Example 3**

25 This example describes the preparation of a base coating that contains dexamethasone

Stents were coated with Parylene C™ using a vapor deposition method provided by the manufacturer of the parylene-coating instrument (SCS Madison, Wisconsin). The stent is weighed and then mounted for coating. While the stent is rotating a solution of 1.75mg/ml Poly (ethylene-co-vinyl acetate)(PEVA), 1.75 mg/ml polybutyl methacrylate, and 1.5 mg/ml dexamethasone dissolved in tetrahydrofuran is sprayed onto it. The coated stent is removed from the spray and allowed to air-dry. After a final weighing the amount of coating on the stent is determined.

5

#### **Example 4**

This example describes the preparation of a base coating that contains rapamycin and dexamethasone

10

Stents were coated with Parylene C™ using a vapor deposition method provided by the manufacturer of the parylene-coating instrument (SCS Madison, Wisconsin). The stent is weighed and then mounted for coating. While the stent is rotating a solution of 1.75 mg/ml Poly (ethylene-co-vinyl acetate)(PEVA), 1.75 mg/ml polybutyl methacrylate, 0.75 mg/ml rapamycin and 0.75 mg/ml dexamethasone dissolved in tetrahydrofuran is sprayed onto it. The coated stent is removed from the spray and allowed to air-dry. After a final weighing the amount of coating on the stent is determined.

15

#### **Example 5**

This example describes a stent coating that consists of a base coat containing rapamycin and dexamethasone and a drug-free barrier overcoat

25

A stent is coated as in Example 4. After the coating is thoroughly dried a solution of 2.5 mg/ml polybutyl methacrylate dissolved in tetrahydrofuran is sprayed onto it. It is then air-dried for a final overcoat weight of 150 µg.

#### **Example 6**

30

This example describes a stent coating, which consists of a base containing rapamycin and an overlayer with dexamethasone

5 A stent is coated as in Example 2. A solution of 1.75 mg/ml Poly (ethylene-co-vinyl acetate)(PEVA), 1.75 mg/ml polybutyl methacrylate, and 1.5 mg/ml dexamethasone dissolved in tetrahydrofuran is sprayed onto it. The coated stent is removed from the spray and allowed to air-dry. The final weight of each layer is typically 250 µg for a total coating weight of 500µg.

10 **Example 7**

This example describes a stent coating, which consists of a base containing dexamethasone and an overlayer with rapamycin

15 A stent is coated as in Example 3. A solution of 1.75 mg/ml Poly (ethylene-co-vinyl acetate)(PEVA), 1.75 mg/ml polybutyl methacrylate, and 1.5 mg/ml rapamycin dissolved in tetrahydrofuran is sprayed onto it. The coated stent is removed from the spray and allowed to air-dry. The final weight of each layer is typically 250 µg for a total coating weight of 500µg.

20 The following examples describe the method and results for testing the *in vitro* release of rapamycin and dexamethasone from coated stent.

25 **Example 8**

This example describes the method for performing the *in vitro* release of rapamycin and dexamethasone from coated stent.

30 Each stent was placed in a 2.5mL of release medium (aqueous ethanol, 25 percent by volume at room temperature) contained in a 13 X 100 mm culture tube with a screw cap. The tube was shaken in a water bath (INNOVA™ 3100,

5 New Brunswick Scientific) at 200 rpm while maintaining ambient conditions. After  
a given time interval (ranging from 15 minutes to one day) the tubes were  
removed from the shaker and the respective stents carefully transferred to a  
fresh 2.5 ml Aliquot of release medium. The new tube was placed on the shaker  
and agitation resumed. A sample was removed from the aliquot, which had  
10 previously contained the stent and placed in a HPLC vial for determination of the  
rapamycin content and dexamethasone, by HPLC.

### **Example 9**

15 This example describes the method for analyzing the release medium for  
rapamycin.

20 The HPLC system used to analyze the samples was a Waters Alliance with a  
PDA 996. This system is equipped with a photodiode array detector. 20 $\mu$ L of  
each sample was withdrawn and analyzed on a C<sub>18</sub> -reverse phase column  
(Waters Symmetry™ Column: 4.6mm X 100mm RP<sub>18</sub>, 3.5  $\mu$ m with a matching  
guard column) using a mobile phase consisting of acetonitrile/methanol/water  
(38:34:28 v/v) delivered at a flow rate of 1.2 mL/min. The column was  
maintained at 60°C through the analysis. Under these analytical conditions  
25 rapamycin had a retention time of 4.75  $\pm$  0.1 minutes. The concentration was  
determined from a standard curve of concentration versus response (area-under  
the curve) generated from rapamycin standards in the range of from 50ng/mL to  
50 $\mu$ g/mL.

30 The results from testing the coated stents described above are shown in Figure  
5.

### **Example 10**

This example describes the method for analyzing the release medium for dexamethasone.

10

The HPLC system used to analyze the samples was a Shimadzu Class-VP Chromatography Laboratory System. This system is equipped with a photodiode array detector. 20 $\mu$ L of each sample was withdrawn and analyzed on a C<sub>18</sub> – reverse phase column (Waters Symmetry™ Column: 4.6mm X 100mm RP<sub>18</sub> 3.5  $\mu$ ). An isocratic mobile phase consisting of methanol/water (55:45 v/v) delivered at a flow rate of 0.8 mL/min. was used for the first 6.5 mins of analysis followed by 100% methanol for 2 minutes; the latter was to ensure removal of rapamycin which is retained on the column. The column was maintained at 25°C throughout the analysis. Under these analytical conditions dexamthasone had a retention time of 5.9  $\pm$  0.1 minutes. The concentration was determined from a standard curve of concentration versus response (area-under the curve) generated from dexamethasone standards in the range of from 40ng/mL to 4.0 $\mu$ g/mL.

15

20

The results from testing the coated stents described above are shown in Figure 6.

25

These and other concepts will are disclosed herein. It would be apparent to the reader that modifications are possible to the stent or the drug dosage applied. In any event, however, the any obvious modifications should be perceived to fall within the scope of the invention, which is to be realized from the attached claims and their equivalents.
